CAUSALITY ASSESSMENT – TASK 3

Drug–Reaction Relationship Assessment

Case Summary

Patient	**35-year-old female**
Suspected drug	Paracetamol
Adverse reaction	Skin rash and itching
Onset	2 hours after taking the drug
Outcome	Recovered after stopping the drug and receiving treatment

Assessment of Causality

Assessment criterion	Finding	Reason
1. Temporal relationship	Yes	Skin rash and itching appeared 2 hours after taking paracetamol, which supports a temporal relationship between the drug and reaction.
2. Dechallenge	Yes	The patient's symptoms improved after paracetamol was stopped. This supports a possible relationship.
3. Alternative causes	Not provided	The case does not provide enough information about other possible causes of the skin rash.
4. Rechallenge	Not reported	here is no information that paracetamol was given again, so rechallenge cannot be assessed.

Final Assessment

Causality classification: POSSIBLE

The reaction has a reasonable temporal relationship with paracetamol, as skin rash and itching appeared 2 hours after taking the drug. The patient's symptoms improved after stopping the drug. However, information about alternative causes is not available and rechallenge was not reported. Therefore, based on the available information, the drug–reaction relationship is classified as Possible.

Short Answer for Task Box

Possible – Skin rash and itching appeared 2 hours after taking paracetamol and improved after stopping it. However, alternative causes cannot be ruled out and rechallenge was not reported.
